Abstract

A substantial body of empirical evidence indicates that interactional context has a key influence on the form and interpretation of language. This paper provides an overview of a series of experiments which indicate that interactional context also plays a key role in the interpretation of drawings and sketches. Two experimental graphical communication tasks, analogous to definite reference tasks, are described. The findings from these tasks show significant parallels between the mechanisms of co-ordination in graphical dialogue and natural language dialogue. Specifically; participants match on drawing types above chance, recurrent 'graphical referring expressions' reduce with repetition in an interaction, direct interaction is necessary to sustain the use of more abstract drawings, and community-specific graphical conventions can be shown to emerge in experimental 'sub-communities'.

Interactional Context in Dialogue

Conversation is a, if not *the*, key context of understanding for language. People's use of language to represent objects, events and situations is sensitive to, amongst other things; who they are speaking to, the mutual availability of referents, the history of their conversation and their (dis)joint membership of cultural and linguistic sub-communities (Hymes, 1972; Clark, 1998). Evidence for the direct influence of interactional context on interpretation and understanding comes from a variety of sources (see Krauss and Fussell, 1996, for a review). One example is provided by work on the Collaborative Model of dialogue (Schober and Clark, 1989; Clark and Wilkes-Gibbs, 1986). Wilkes-Gibbs and Clark (1992) have shown that full understanding of referring expressions depends on the degree of active participation in conversation by speaker and addressees. Non-active participants in a conversation, such as passive side-participants, overhearers, or bystanders, are less able to understand referring expressions than active participants. This is observed even when, in gross informational terms, they are equivalent to active participants.

A second example of the influence of interactional context comes from studies of conceptual and lin-

guistic co-ordination in dialogue. Garrod and Anderson (1987) have shown that conversational partners tend to match or 'entrain' on the form and interpretation of utterances during interaction. Where several types of semantically distinct referring expressions are possible for describing a location, people show a strong preference for matching the type of expression used by their conversational partner. Brannigan, Pickering and Cleland (2000) have observed similar entrainment effects with syntax. Garrod and Anderson (1987) argue that these dialogue phenomena reflect the operation of a basic dialogue co-ordination mechanism which simplifies the processes of production and comprehension in interaction.

Intuitively, it might be supposed that graphical representations would be less sensitive to interactional context. One reason for this is that the production and use of drawings and sketches is normally treated, and analysed, as an activity more akin to monologue than dialogue (cf. Scaife and Rogers, 1996). There is evidence, however, that this underestimates both the actual and potential use of drawing activities as a mode of interaction. Anecdotally, drawings are often incrementally produced and modified as part of a conversational exchange. For example, sketch maps and explanatory diagrams form a familiar extension of many routine conversations.

van Sommers (1984) provides evidence from a questionnaire study that approximately half of routine, non-work, drawing activities take place with or for an audience. Although van Sommers does not report how often these exchanges involve direct graphical exchanges, his findings demonstrate the variety of interactional contexts in which drawing occurs. The most frequently cited category is the production of sketch maps of a local area, either as part of an explanation or in order to give directions. The second most frequently cited category relates to activities with children including; games and amusements, teaching or helping with homework and helping children learn to draw. Additional categories of 'public' drawing include; sketching of hair, makeup and clothing, sketching house plans, drawing to express feelings, defacing pictures and drawing people.

The collaborative development and modification of sketches is a feature of many specialised work related interactions, such as architect-architect and architect-client (Neilsen and Lee, 1994). We estimate that in the architects' practice studied by Healey and Peters (2001) approximately 30% of daily drawing activities occurred as an integrated part of a conversational exchange. Engle (1998) provides experimental evidence that graphics, gesture and language combine in explanatory dialogues to create composite communicative signals (Clark, 1996). Overall, there is a *prima facie* case that sketches and drawings are often closely integrated into interaction and that this may have significant implications for their interpretation.

A second possible reason for scepticism about the role of interactional context in the interpretation of sketches and drawings is the intuition that drawings and sketches are easier to interpret than language. Arguably, many of the interactional influences on language interpretation are associated with the conventional nature of linguistic representation. Co-ordinated interpretation of utterances requires the concerted application of conventions. Interaction is used to maintain and modify those interpretations. Drawings and sketches can exploit iconicity to provide a less arbitrary form of representation. Consequently, we might suppose that they would be less dependent on interaction to secure their interpretation. While this might be true in cases such as sketches of buildings or people, it does not cover the range of uses to which sketches and drawings are put. Explanations involving sketches of Venn diagrams or Euler circles provide perhaps the most obvious counter-example.

The present paper summarises the findings from a series of experiments which, considered together, provide evidence that the interpretation of drawings and sketches is sensitive to interactional context. In particular, that interactional context has marked effects on the form, interpretation and understanding of sketches; and that the mechanisms and processes that give rise to these effects show important parallels to those identified for natural language dialogue.

Interactional Context in Graphical Dialogue

The findings reported below are drawn from experiments involving two basic referential communication tasks, the Concept Drawing Task and the Music Drawing Task, in which pairs of subjects communicate about a variety of concepts using exclusively graphical means. These tasks can be thought of as two-way or conversational variants of the party game 'Pictionary'.

The Experimental Tasks

The basic Concept Drawing Task uses an ordered list of twelve concept words drawn from the categories; places (e.g., "theatre", "art gallery", "museum"), people (e.g., "Robert de Niro", "Arnold Schwarzenegger", "Clint Eastwood"), television programmes (e.g., "drama", "soap-opera", "cartoon"), objects (e.g., "television", "computer microwave"), and abstract concepts (e.g., "loud", "homesick", "poverty"). One participant, the 'Drawer', is given an ordered list of twelve words. Their partner, the 'Chooser', is presented with an unordered list of the same twelve words plus four distractors. The task is for the Drawer to take each word in turn from their list and produce a sketch of it so that their partner, the Chooser, can identify the concept depicted. The aim is for the Chooser to determine the original ordered list of twelve concept words that the Drawer started with.

The basic Music Drawing Task is similar to the Concept Drawing task but uses pieces of music in place of concept words. The pieces are relatively unknown 30 second piano solos in a variety of genres and styles. In the typical procedure, the Drawer and the Chooser are seated in separate rooms. The Drawer listens to a target piece of piano music and produces a sketch of it. The Chooser has two pieces of music, the target and a distractor, and tries to select which piece is the one depicted by the Drawer. Playback of the pieces is self-paced and all drawing takes place on a shared virtual whiteboard which logs the drawing data for analysis (Healey, Swoboda, King, 2002).

In both tasks, subjects are free to draw anything they like; the only restriction is that they do not use letters or numbers. The types of drawing produced for each concept or piece of music varies substantially between pairs, some examples are provided in Figures 1, 2 and 3. All things being equal, each pair tends to establish their own conventional solutions to the communication problems posed by the task. Subjects appear to find both tasks enjoyable and engaging and perform them with above chance accuracy.

Effects of Interactional Context

A number of experiments have been performed using these tasks which suggest important parallels between the effects of interactional context on graphical and verbal dialogue. Here we provide an overview of the findings from these experiments and discuss their implications for investigations of graphical representation and models of human interaction.

Interactional Entrainment. One of the simplest pieces of evidence for effects of interactional context on the use of drawing comes from the Music Drawing task. Participants in this task produce drawings

Figure 1: Example Abstract drawings from Two Successive Trials of the Music Drawing Task

Figure 2: Example Figurative Drawings from Two Successive Trials of the Music Drawing Task

that can be reliably classified into two basic types¹; ‘Abstract’ and ‘Figurative’ ($Kappa = 0.9$, $N = 287$, $k = 2$). Abstract drawings, illustrated in Figure 1, typically involve graph-like representations of e.g., pitch, melody, rhythm or intensity. By contrast, Figurative drawings, illustrated in Figure 2 typically depict recognisable objects, figures or scenes. Where pairs of participants in the task both take the role of Drawer (either by alternating roles or in manipulations in which both participants draw at the same time) they show a reliable tendency to match each other in their use of drawing the Figurative and Abstract drawing types (Healey, Swoboda, Umata, & Katagiri, 2001). As noted above, this pattern of entrainment between the participants in an interaction is also established for semantic and syntactic aspects of utterances in dialogue (Garrod and Anderson, 1987; Brannigan, Pickering and Cleland, 2000). Garrod and Anderson (1987) argue that entrainment constitutes a basic mechanism through which conceptual co-ordination is achieved in dialogue.

Contraction of Recurrent References. The procedure for the Concept Drawing task typically requires pairs to repeat the same set of twelve target words, in different orders, over several trials. This manipulation ensures that each word is drawn, and

¹For ease of exposition a third, ‘Composite, type is not discussed here

Figure 3: A Sequence of ‘Robert deNiro’s from the Concept Drawing Task

identified, several times by each pair. This is designed to reproduce the procedure followed by Clark and Wilkes-Gibbs (1986) who investigated the production of recurrent (verbal) referring expressions by conversational partners. Clark and Wilkes-Gibbs found that both the average number of words and average number of turns used to refer to a target item (in their case a tangram figure) rapidly declined with the number of repetitions. Experiments with the concept drawing task show the same pattern of reduction. This is illustrated in Figure 3 which shows a sequence of four trials (ordered left to right and top to bottom). Where target concepts recur, the drawings that represent them quickly become simplified. This is indexed both by simple quantitative measures such as the amount of ‘ink’ and number of lines used, their complexity as estimated by human judges and calculations of their visual complexity.²

Experiments to evaluate the effects of these contractions on the intelligibility of the drawings for non-participants are currently in progress. However, it appears likely that they will have a substantial effect. The first drawing in Figure 3 has a number of elements that might allow a non-participating observer to guess the identity of the individual depicted. For example it includes a sketch map of Italy, sketches of a TV and VCR, and an image of a taxi (which refers to a de Niro film). By contrast, the last sketch in the sequence, consisting of a star and a dollar sign would be much harder to decipher.

Effects of Direct Interaction. Experiments with the Music Drawing task have investigated the influence of level of communicative interaction be-

²The analysis of visual complexity is based on a psychophysical measure developed by Pelli Burns Farell and Moore (in press) and is based on the formula: Complexity = Perimeter² / Ink.

tween participants on the type of drawing (Abstract or Figurative) that they produce. The basic contrast is between an interactive and non-interactive version of the task (Healey et al., 2001; Healey, Swoboda, Umata and Katagiri, forthcoming). In the non-interactive version, subjects alternate between acting as Drawer and Chooser on each trial and the whiteboard is configured to prevent the Chooser from drawing. In this version of the task each trial approximates to a single turn in the communicative exchange. In the interactive version the task is altered so that both members of a pair draw at the same time. They have one piece of music each and must determine, using only drawing, whether their pieces are the same or different. In this case there is a richer communicative exchange. In addition to producing drawings of their pieces, subjects employ devices such as arrows, underlining, and circling to query and revise various aspects of their drawings. Each trial in the interactive task thus approximates to a number of ‘conversational’ turns.

The effect of the difference in level of communicative interaction can be seen in Table 1 (the ‘Composite’ category refers to drawings that combine Figurative and Abstract elements). Where both members of a pair can interact directly on the whiteboard, they rely primarily on the Abstract drawings. In the non-interactive task, where they are alternating between drawing and choosing, they rely primarily on Figurative drawings.

Table 1: Distribution of Drawing Types in the Music Drawing Task

Task	Drawing Type		
	Abstract	Figurative	Composite
Interactive	59%	21%	16%
Non-Interactive	27%	64%	8%

Further evidence for the importance of direct interaction comes from analysis of the logs of drawing activity captured by the shared whiteboard (Healey, Swoboda, Umata and Katagiri, forthcoming). The Abstract and Figurative types are not distinguishable in terms of the number of lines or ink (pixels) involved in producing them, nor in terms of the accuracy of responses associated with drawings of each type. This undermines an explanation of their distribution based on considerations of the efficiency or effectiveness of the two drawing types. However, drawing activities overlap approximately 20% more when subjects produce Abstract drawings than when they produce Figurative drawings. This suggests it is the availability of specific mechanisms of communicative interaction, such as the circling and underlining of each others drawings, that is critical

to the co-ordinated use of the Abstract drawings.

Community-based Conventions. Perhaps the most interesting parallel between graphical and verbal dialogue comes from experiments on the emergence of graphical conventions in experimental ‘sub-communities’ (cf. Garrod and Doherty, 1994).

Data from an unpublished experiment with the Music Drawing task demonstrates that, for the Music Drawing task at least, the patterns of co-ordination in drawing style that emerge within sub-communities are specific to those sub-communities (cf. Healey, 1997). The experiment takes place in two phases. In the first ‘convergence’ phase experimental sub-communities consisting of sub-groups of six people are formed. Subjects themselves are unaware of this sub-group manipulation, from their perspective the experiment consists of a series of rounds of Music Drawing with a different partner each time. During the convergence phase, the composition of pairs is controlled so that they are always made up of individuals from within the same sub-group. This continues for four rounds thus allowing for a history of interactions to build up within each sub-group. On each round subjects perform the interactive version of the Music Drawing Task for 12 trials.

The second, experimental, phase occurs in the fifth round. In this round two conditions are compared; same-group pairs who are composed, as before, of subjects from within a single sub-group and cross-group pairs who are composed of subjects drawn from different subgroups.³ Same-group and cross-group pairs have equivalent task experience and, as noted, are unaware of any sub-group manipulation. Nonetheless they are reliably different in their use of the Drawing types. Multinomial regression analysis shows a reliable effect of the group manipulation on the distribution of Drawing types ($\chi^2_{(3)}=25.44, p=0.00$). The percentages are shown in Table 2.

Table 2: Use of Drawing Types in Pairs Drawn from the Same or Different Subgroups

Task Version	Drawing Type		
	Abstract	Figurative	Composite
Same-group	62.7%	11.1%	18.1%
Cross-group	41.3%	32.9%	15.8%

These results indicate that the co-ordination on particular drawing types that develops within the experimental sub-communities is community-

³The original design employed three experimental subgroups but for ease of exposition only two are reported here.

Figure 4: Reduction in Visual Complexity of Concept Drawings with Repetition in a Round (B1-B3 = Blocks of recurring items within a round)

specific. The conventions for graphical representation that develop within these experimental sub-communities do not readily transfer to interactions outside those sub-communities. Subjects in the cross-group interactions use a more mixed profile of drawing types. This suggests that the graphical conventions established within a sub-communities are less effective for communication outside those communities. This parallels results, reported in (Healey, 1997), for verbal dialogues about spatial locations. The types of spatial referring expressions established within sub-communities during the corresponding convergence phase also proved unstable in ‘cross-group’ interactions.

Data from a community-based version of the Concept Drawing Task also suggests parallels between communities of graphical and linguistic communicators. The task requires a community group of 8 participants to communicate with each of the other 7 over an extended period of time. In the first round of the experiment the 8 work in 4 pairs with both participants drawing each concept 3 times over the course of the round. In the second round the 8 participants are re-paired and again draw the concepts 3 times. After each round they are re-paired again until every participant has encountered each of the others once and only once.

Figure 4 shows how drawings become increasingly simple (on the Pelli et al. measure) as the experiment proceeds. In the first 3 rounds this simplification process occurs across repetitions of the drawings (shown along the x axis of the figure). However, as the shared interaction within the community begins to develop (i.e., after round 4) the initial drawings in a round become as simple as the final drawings in the round. A similar pattern of results emerges for the communicators accuracy at identifying the concepts conveyed by their partners drawings. These findings

are consistent with the idea that as a community becomes established through a common history of interaction so the drawings become conventionalised within the community: Drawings become simpler and more readily interpreted by the members of the community.

The implication of these results is that the processes which establish the conventions for producing and interpreting drawings and verbal descriptions operate in a manner that is directly tied to the character and pattern of interactions in which they were developed and used.

Discussion

The ambition of providing an overview of a number of experimental results dictates that much important detail has been elided from the descriptions of experiments and results provided above. Nonetheless, the results summarised above consistently point to the importance of interactional context in graphical communication.

Like referring expressions in conversation, the form and interpretation of drawings is systematically influenced by the character of the interaction in which they occur. Participants in interactions show a strong tendency to match each others representational style and type. If items recur in an interaction, pairs also tend to develop increasingly abbreviated ways of representing them that are difficult for third parties to interpret. These patterns of change in the form of drawings obtain independently of the particular concept or item being represented. In addition to these basic co-ordination processes of entrainment and abbreviation, there is also evidence that level of direct graphical interaction available to participants affects the form of representations they use. In particular, the ability to localise, mark up and re-draw elements of each others’ drawings appears to be important to the sustained use of more abstract representations. Lastly, this paper has presented evidence that interactions within sub-communities lead to the development of community-specific conventions for graphical interaction.

The programmatic rationale for investigating tasks, such as those described above, that involve exclusively graphical communication is the potential they offer for making comparisons with other modes of interaction. The results summarised above suggest that this strategy is productive. There appear to be significant parallels between the mechanisms that underpin communicative co-ordination in exclusively graphical and verbal exchanges. As noted above, some of these findings can be accounted for in terms of the collaborative model of grounding Clark and Wilkes-Gibbs (1986), Clark (1996) and input-output coordination model Garrod and Anderson (1987), Garrod and Doherty (1994). The importance of interactional mechanisms, such as lo-

calisation, to graphical communication also suggests possible parallels with the mechanisms of conversational repair Sacks, Schegloff and Jefferson (1974), Schegloff (1992). The viability of applying these explanations to the details of graphical communication is the subject of further work.
